POLICY DEPARTMENT A: ECONOMIC AND SCIENTIFIC POLICY

Recent Trends in Energy Prices

IN-DEPTH ANALYSIS

Abstract

After a dramatic fall in 2014, oil and fuel prices in euro terms increased in the first part of 2015, before decreasing again and since mid-2015 to record low levels, similar to early 2015. However, retail gas and electricity prices - which traditionally follow similar trends with some delay stabilized or in some cases even increased, in large part due to higher taxes. Large differences persist amongst EU Member States and commodities. Conversely, most experts claim that fossil fuel prices can be expected to stay "low for long." Notwithstanding important recent progress in developing renewable fuel sources, low fossil fuel prices could discourage innovation in and adoption of cleaner energy technologies.

This paper was prepared by Policy Department A for the Industry, Research and Energy Committee (ITRE).

This document was drafted for the European Parliament's Committee on Industry, Research and Energy (ITRE).

1. GENERAL TRENDS AND OBSERVATIONS

High level of uncertainty remains.

The recent fall in oil prices, continued geopolitical instability and the December 2015 Paris climate negotiations are witness to the dynamic nature of energy markets. In a time of high volatility and uncertainty, understanding the implications of the shifting energy landscape for economic and environmental goals and for energy security is of paramount importance. To facilitate this process, this publication presents updated energy pricing data for EU Member States, as well as some expert insights on the prospects for fossil fuels, renewables, and the power sector. While the fall in energy prices has been an economic boon for many energy importers - not the least the European Union - alleviating fiscal strains and allowing money to be freed up to stimulate other parts of the economy, it by no means has eliminated the uncertainty about growth prospects. In Europe, the legacy of the economic downturn continues to subdue demand. From an energy perspective, the economic structure of individual EU Member States - and contribution that different economic sectors make to total GDP can be as important as the overall rates of growth - as the extent to which they use energy as an input to generate economic output (or value added) varies significantly.

Price is a key driver of energy trends.

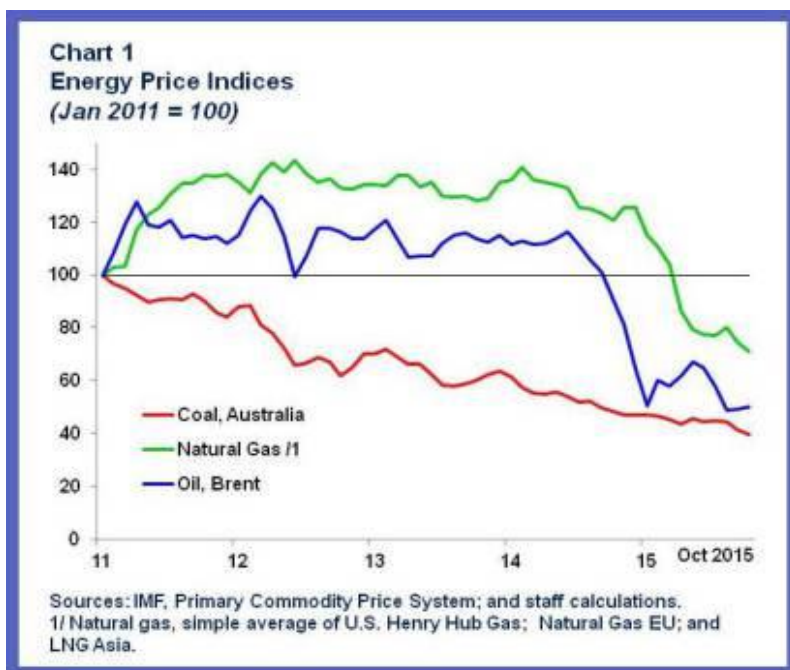

Prices paid by consumers affect the amount of each fuel they choose to consume and their choice of technology and equipment to provide an energy service. Conversely, the price that producers receive, which is not dealt with in this paper strongly influences their investment decisions and therefore the level of future production. Retail prices in end-uses take into account local market conditions, including taxes, excise duties, carbon prices and relevant subsidies. The price paths for fuels also reflects the differences in the policies introduced to address energy security, environmental and other issues, and their respective impacts on supply and demand.

Oil prices are expected to stay low for an extended period of time.

Recently, a global oil supply glut has been created, notably as shale oil production, made possible by hydraulic fracturing ("fracking") has added about 4.2 million barrels per day (about 5% of the total) to the crude oil market. Experts say that shale oil is leading to shorter and more limited oil-price cycles. This is explained by the fact that shale requires a lower level of sunk costs than conventional oil, while the lag between first investment and production is much shorter. Furthermore, shale is still at a relatively early stage of its industry life cycle, where the scope for learning is substantial, as shown by production levels that have proven resilient thanks to phenomenal efficiency gains forced by the big fall in oil prices. In addition, other factors are putting downward pressure on oil prices: change in the strategic behaviour of the Organization of Petroleum Exporting Countries (OPEC), the projected increase in Iranian exports, the scaling down of global demand (especially from emerging markets), the secular drop in petroleum consumption in the United States, and some displacement of oil by substitutes. These likely persistent forces, point to a "low for long" price scenario, even after the supply legacy left by the high-price era of the 2000s has dissipated. Futures markets, which show only a modest recovery of prices to around EUR 55 a barrel by 2019, support this view.

Coal and natural gas have similarly seen price declines that look to be long-lived.

Coal and natural gas are mainly inputs to electricity generation, whereas oil is used mostly to power transportation, yet the prices of all these energy sources are linked, including

through oil-indexed contract prices. The shale gas boom has resulted in record low prices. The recent discovery of the giant Zohr gas field off the Egyptian coast is expected to have repercussions on pricing in the Mediterranean region and Europe, and there is significant development potential in many other locales, notably Latin America. Coal prices also are low, owing to oversupply and the scaling down of demand, especially from China, which burns half of the world’s coal.

Renewables account for a small share of global primary energy consumption, which is still dominated by fossil fuels.

Table 1: Energy consumption (2014)

**Share of Primary Energy Consumption in 2014
(percentage points)**

	Oil	Natural Gas	Coal	Nuclear Energy	Renewables
World	33	24	30	4	9
United States	36	30	20	8	5
China	18	6	66	1	10
European Union	37	22	17	12	13

Sources: BP Statistical Review of World Energy, June 2015; and IMF staff calculations.

Technological innovations have unleashed the power of renewables such as wind, hydro, solar, and geothermal. Even Africa and the Middle East, home to economies that are heavily dependent on fossil fuel exports, have enormous potential to develop renewables. Progress in the development of renewables could be fragile, however, if fossil fuel prices

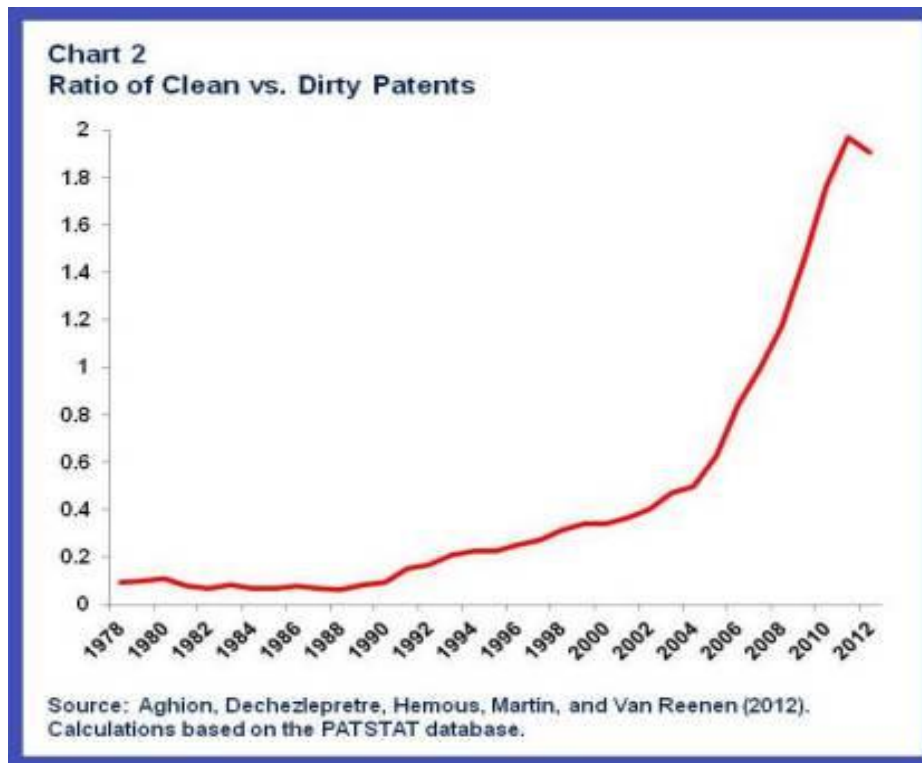

remain low for long. Renewables account for only a small share of global primary energy consumption, which is still dominated by fossil fuels: about 30% each for coal and oil, 24% for natural gas (see Table 1). But renewable energy will have to displace fossil fuels to a much greater extent in the future to reduce climate risks. Unfortunately, the current low

prices for oil, gas and coal may provide scant incentive for research to find even cheaper substitutes for those fuels. There is strong evidence that both innovation and adoption of cleaner technology are strongly encouraged by higher fossil fuel prices. The same is true for new technologies for mitigating fossil fuel emissions.

The current low fossil fuel prices delays the energy transition.

The current low fossil-fuel price environment will certainly delay the energy transition (see Chart 2). That transition from fossil fuel to clean energy sources is not the first one.

Earlier transitions were those from wood/biomass to coal in the eighteenth and nineteenth centuries, and from coal to petroleum in the nineteenth and twentieth centuries. One important lesson is that these transitions take a long time to complete.

2. BRENT OIL PRICES

Back to the price level of early 2015.

Oil prices have dropped by over 50 % between early 2014 and the beginning of 2015 (see Chart 3). In early 2015, the volatility in the euro/dollar rate caused a rise in euro denominated crude oil. In the second half of the year, however, the oil Brent price in euro fell to the levels of the beginning of the year. A commonly held view in the oil industry is that “the best cure for low oil prices is low oil prices.” The reasoning behind this adage is that low oil prices discourage investment in new production capacity, eventually shifting the

oil supply curve backward and bringing prices back up as existing oil fields - which can be tapped at relatively low marginal cost - are depleted. However, due to new technologies, the dynamic adjustment to low oil prices may be different this time.

3. FUELS

3.1. Unleaded petrol

Prices fell in almost all EU Member States, with an increasing tax component.

In September 2015, the median unleaded petrol price, including taxes, amounted to 131 eurocent for the euro area and 125 eurocent for the EU 28. Part of the difference is due to the tax component, which is 1.2 percentage points higher in the euro area than in EU 28. The highest price was in the UK and the Netherlands at 152 eurocent per litre, whilst the lowest price was in Estonia at 108.4 eurocent per litre. Over the previous three years, trend prices have been gradually falling, in tandem with an increase in the tax component, in particular in the previous year and in all EU Member States, without one single exception.

3.2. Diesel

Prices fell across the board at double the rate of unleaded petrol prices, tax component increasing too.

The Median EU Member State's average Diesel price including taxes in September 2015 amounted to 113 eurocent per litre. The lowest price was in Luxembourg at 100 cents per litre. The highest price was in the UK at 150 eurocent per litre, which is primarily due to a tax component (69%), much higher than the 54% average EU 28 and Euro Area tax component. Median euro area and median EU prices of Diesel fell at about double the rate of unleaded petrol prices in the year to September 2015.

4. GAS

Fall in gas prices mitigated by large tax increases.

In the year to the first half of 2015, the median gas price for euro-area medium-size consumers, amounted to 4.99 eurocent per kWh for the euro area without taxes and 6.78 eurocent including taxes. Net-of-tax gas prices fell markedly since the end of 2013 in most EU Member States, but tax increases 'masked' a large part of the decrease. The highest price (taxes included) was in Sweden and Portugal at respectively 11.3 and 9.8 eurocent per kWh, whilst the lowest price was in Romania at 3.1 eurocent per kWh. A large part of the price gap is due to the impact of exchange rate developments (e.g. UK) and significant differences in the tax component of the consumer price. In most EU Member States, consumers pay a lower per unit price when they use higher volumes.

Table 4: Domestic gas prices in the EU for medium consumers eurocent per kWh (excluding taxes)

5. ELECTRICITY

Electricity price developments vary across EU Member States with significant tax increases in most countries.

In the first half of 2015, the median electricity price for medium-size consumers, including taxes, amounted to 17.6 eurocent per kWh for the euro area and 17.1 eurocent for the EU 28. The highest price was in Denmark at respectively 30.7 cents/kWh, whilst the lowest price was in Bulgaria at 9.4 eurocent per kWh. Electricity prices (without taxes) fell in most EU Member States in the year to mid-2015. However, tax hikes mitigated this fall in so far that prices including taxes slightly rose in almost all EU Member States. A large part of the price gap amongst Member States is due significant differences in the tax component of the consumer price. Here as well, consumers pay often a lower per unit price when they use higher volumes.

6. RENEWABLES

Steady increase, and with large differences amongst EU Member States.

Over the last ten years the consumption of renewable energy steadily increased in all Member States and hence in the EU as a whole. The reason lies mainly in the launch of variety of EU-wide and national initiatives to combat climate change and comply with energy objectives. For instance, renewable support schemes put in place encourage investments in solar photovoltaic and onshore wind. Some Member States traditionally make considerable use of renewable energy, with approximately one third of their energy consumption coming from renewable sources (Finland 29%, Latvia 32%, Sweden 40% in 2004), while others used renewables significantly less (Malta, Luxembourg, UK, Netherlands, Belgium, consuming less than 2% in 2004). These figures have increased in all Member States over the years. The most recent data show that Sweden is outperforming all Member States, with renewable energy consumption accounting for more than half of the gross energy consumption. It is followed by Finland, Latvia and Austria that hold levels at above 30%. Member States that typically rely less on renewables have multiplied usage over the period of observation (2004-2014) by up to four times in certain cases.

Table 8: Share of renewable energy in gross final energy consumption in percentage (2004-2014)
