Subject: Vaccines containing metal contaminants

Tests of blood from people vaccinated against SARS-CoV-2 almost always reveal the presence of metal contaminants in the vaccine concerned, which may not be lethal but are not conducive to good health either. These impurities can likely be explained by the poor quality of the vaccines - itself the result of producing them too quickly and in too large volumes. Production would usually immediately be stopped if impurities were found.

1. Why has that not yet happened in this case, especially given that SARS-CoV-2 is not particularly dangerous and has an almost 100% survival rate at all ages?
